

The Arctic boundary layer

Interactions with the surface, and clouds, as learned from observations (and some modeling)

Michael Tjernström

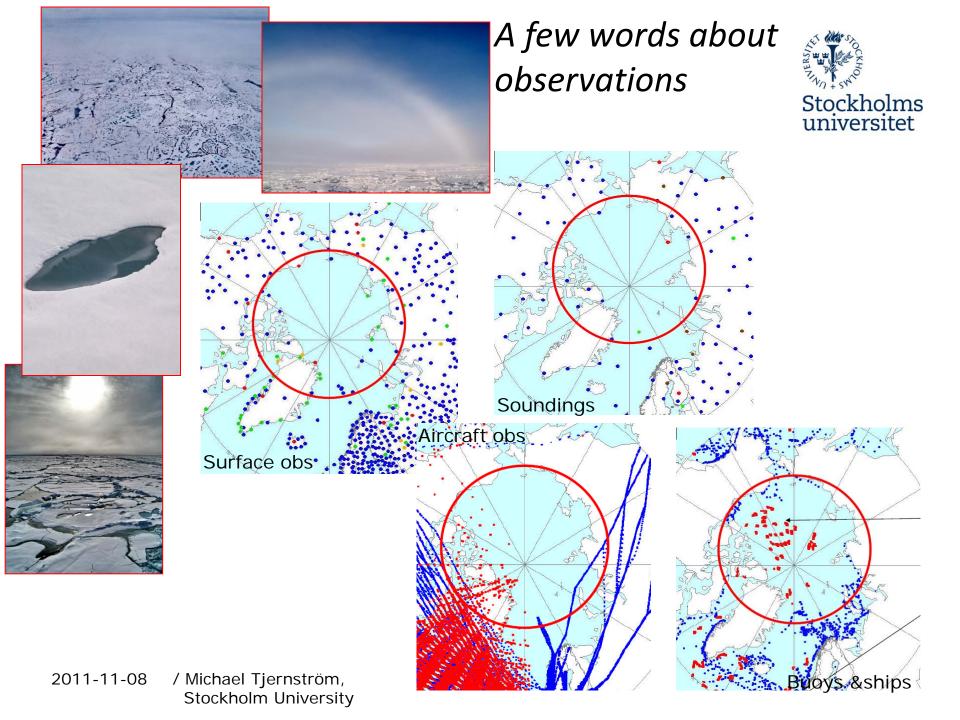

Department of Meteorology & the Bert Bolin Center for Climate Research, Stockholm University

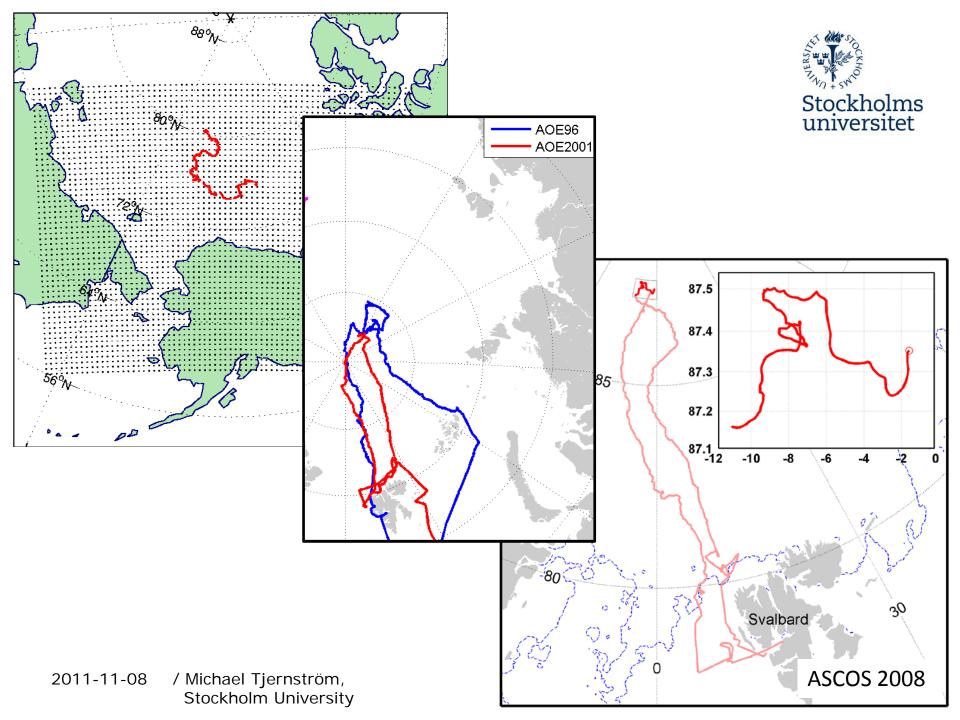

With the help of many: Ola Persson, Chris Fairall, Ian Brooks, Matthew Shupe, Thorsten Mauritsen, Joseph Sedlar, Cathryn Birch and many, many others

Context

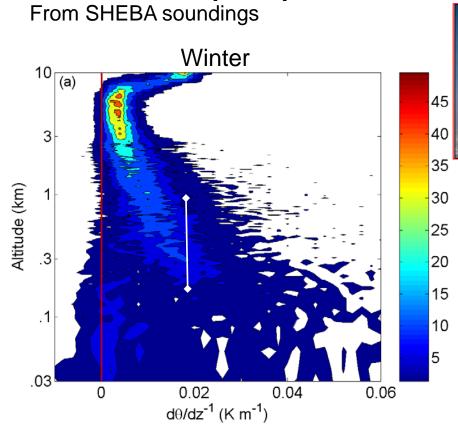

- A few words about observations, or the lack thereof
- Boundary-layer structure
- Interaction with the surface: the seasonal story and what's below
- Interactions with clouds
- Some modeling here and there

All seasons: Stable layer 200 m to ~2 km, near neutral 5-8 km & often near neutral PBL.

Winter: Additionally strong surface inversions ~ 50% of the time

Some reflections...

- What we think we know about small scale features such as low-troposphere vertical structure, clouds and surface fluxes rests on very "thin ice". As a consequence modeling with out observational constraints is problematic; even reanalysis is difficult
- Some things stand out:
 - The over-all boundary-layer structure is dominated by near-neutral conditions, but strong lasting surface inversions do occur in winter
 - -Three surface coupling regimes: melt (summer, fixed T_s), non-melt (spring, responsive T_s) and polar night (winter, no sun).
 - Near-surface moisture remains close to saturation almost always!
 - In winter, conduction through ice & snow is as important as sensible heat flux and snow thickness is critical
 - Low clouds dominate, but clouds are sometimes optically thin. In summer this is because of sometimes very low aerosol concentrations while cloud-water phase is also important, especially in winter
 - -Surface energy balance is dominated by (LW) radiation while turbulent heat fluxes are small ⇒ focus more on the momentum flux?
